For express-analysis of oils high weight components (asphaltenes, resins, heavy isoparaffins) existing methods of analysis – near infrared spectroscopy, X-rays and mass-spectrometry are not fast enough for operative control and require sample preparation. Nuclear magnetic resonance spectra also can not give information about nanodimensional high molecular compounds and cannot be used as method of control. But optimization of technology, prevention of accidents and ambient protection require express-control of fuels and raw materials. Such opportunities posses nuclear (proton) magnetic resonance relaxometry (NMRR) method, which is demonstrated on the examples of several physic-chemical properties of oils and bitumen determination [1]. NMRR also is unique for slow motions study in aggregates, especially by spin-spin relaxation times T2i. But it was found, that determined by NMRR concentration of asphaltenes and paraffins, differs from determined by ISO 3405-88. This can be explained by restrictions of molecular motion in nondimensional structure fragments and by shortening of relaxation times below the opportunities of NMR-relaxometer (due to dead time of probe coil). We suggested [2, 3] to «warm up» molecular motion in this fragments by irradiating samples at the wave length of their energy absorbance. This will increase amplitude of molecular motions and so selectively increase their relaxation times, which give opportunity to measure them with higher sensibility using NMR-relaxometer.

Effect of laser irradiation in visual and near infrared range of spectra on relaxation times raise DT*2i = T*2i – T2i (where T*2i and T2i are times under and before irradiation) in natural oils is reported. Dependence of NMR-parameters from oil components concentration, affected by irradiation were studied and quantitatively interpreted in terms of energetic levels populations behavior. Correlations of DT*2i with components concentration were revealed.

ABOUT METHOD OF INCREASING BIOCHEMICAL ACTIVITY OF LACTOSE FERMENTATIVE YEAST

Olmoeva V.D., Khamnaeva N.I.

Lactose fermentative biological objects, being technically useful microflora, should have technological characteristics. In this regard search of new methods of their cultivation, increasing the efficiency of fermentation process is very important.

Many researchers have been studying influence of medium formulation on microorganisms’ growth. So, Zalashko got the best results of cultivating strain S. Fragilis on milk whey adding 0,75 % of ammonia sulphate, 0,5 % of monosubstituted potassium phosphate and 0,1 % of yeastrel (37,05). Wasserman et al. got the maximum crop by adding 0,5 % of ammonia sulphate, 0,5 % of monosubstituted potassium phosphate and 0,1 % of yeastrel to milk serum [1].

Abramov S.A., Kostenko S.T, Khalilova E.A., Islamova F.I., Omarov M.M. [3] grew yeast on nutritional medium where as mineral and organic nutrition geothermal water of non phenolic class was used, watered down up to mineralization 4.0-4.2 g/l. The method allows decreasing spending deficit components of mineral and organic nutrition.
